

AI-Based Academic Research Analytics

Authors: Khadija-tu-Zohra, Research Analytics Group

Abstract

This short study looks at how basic artificial intelligence methods can be used to understand academic research data. The focus is on finding simple patterns in publications and helping users view research activity more easily.

Introduction

Universities maintain information about researchers, publications, departments and projects. When this information grows, manually checking it becomes difficult. A small analytics system can help organize the data and show useful trends.

Method

Publication records were grouped by year, research area and department. Simple data analysis was used to compare the number of records and identify areas with more activity.

Observation

The results suggest that even basic analytics can make research information easier to explore. Visual summaries are especially useful when many records are stored in one system.

Conclusion

AI and simple analytics can support academic information systems without making the system unnecessarily complex. Future work can explore better prediction and recommendation features.
